

Keeping time

How do geologists determine the order of events?

How do geologists determine the age of a rock?

How do geologists determine the age of the Earth?

The Relative Order of Events

- Relative age = one thing is older or younger than another (versus “absolute age, which is establishing the date of something).

These layers are younger than..

these layers

Steno's Laws (you need to know these)

- Principle of Superposition - the layer of sediments on the bottom has to be older than the layer above it.
- Principle of Original Horizontality - layers of sediment are laid down flat
- Principle of Cross-Cutting Relationships - if sedimentary layers are cut by an intrusion or fault, the layers have to be older.
- Principle of Inclusions - if an igneous rock has pieces of another rock in it, the pieces have to pre-date the rock that includes them.

Law of superposition

Layers at the top of a sequence have to be younger than the layers at the bottom

Law of original horizontality

Sediments are laid down horizontally. If the layers are tilted, the tilting happened after they were deposited

Copyright © 2006 Pearson Prentice Hall, Inc.

The sediments that are being deposited in the river are being laid down flat, not up the sides of the canyon

Law of lateral continuity

Sedimentary rock layers extend laterally until they gradually change to another rock type...they don't just "stop."

The sand on the shore of North Beach extends out into the lake until they gradually become smaller grains and become another type of sediment; the beach environment doesn't just end.

Law of inclusions

The clast of igneous rock has to be older than the sedimentary rock that contains it

Law of cross-cutting relationships

Copyright © 2006 Pearson Prentice Hall, Inc.

If rock layers are cut by faults or other rock types, the rock that is cut has to be older than what cuts through it.

Copyright © 2006 Pearson Prentice Hall, Inc.

(this is an igneous intrusion, or basalt dike, cutting through granite)

Which of Steno's Laws do you see "in action" in this photo?

Two more ways to establish
relative ages:

Unconformities

Principle of Faunal Succession

A famous unconformity:

Scottish geologist James Hutton recognized that a huge amount of time must have lapsed between when the layers in the foreground were laid down flat, then tilted and the next layers were deposited, and both tilted.

Siccar Point, Scotland

An unconformity = a time when either no sediment was deposited, or it was deposited but then eroded (you need to know these definitions)

- Angular unconformity = the older layers were tilted and eroded before the next layers
- Nonconformity = the time between when an igneous or metamorphic rock forms and it is then covered by sedimentary layers
- Disconformity = the time between deposition of sedimentary layers, which may involve erosion.

What type of unconformity is this? (the rocks are sedimentary)
Which of Steno's Laws can be applied?

1. First: lower layers are deposited flat
2. Lower layers are folded
3. Unconformity represents period of erosion
4. Upper layers are deposited
5. All layers gently tilted

There are 3 types of unconformities

The diagram illustrates stages in the formation of an angular unconformity. The time required for uplift and erosion of the lower sedimentary layers is not recorded in rocks at this location.

Copyright © 2006 Pearson Prentice Hall, Inc.

1. Angular unconformity

2. nonconformity

Copyright © 2006 Pearson Prentice Hall, Inc.

The black line nonconformity Canyon. Met: plutonic-igneous bottom of the overlain by sedimentary rocks. Approximate of Earth's history the unconformity

The diagram shows how a nonconformity forms. Metamorphic and plutonic rocks form deep below the surface. Erosion removes the overlying rock and then later sedimentary rocks are deposited on the eroded surface.

3. disconformity

The diagram illustrates how a disconformity forms.

The hardest to see because the rock types above and below are the same (sedimentary) and both are flat lying

Apply Steno's laws to establish a sequence of events, oldest to youngest

This is an example of which of Steno's laws?

All the rocks are sedimentary. The black line defines the contact. Is this an unconformity or not; how do you know?

List the sequence of events, from oldest to youngest

Principle of Faunal Succession: fossil plants and animals appear in rocks in a definite succession that represents their evolution on Earth

Trilobites evolved before dinosaurs...so if a rock has trilobite fossils in it it must be older than a rock with dinosaur fossils

Application of the principle of faunal succession...figuring out the age of a sedimentary rock based on the fossils that are in it

X axis = different organisms that are present

Steno's Laws, unconformities and the Principle of Faunal Succession were synthesized to create the geologic time scale, name that we give to various intervals of time in Earth history

In order to put all the changes in Earth history in order, we need to be fluent in this sequence and the ages in millions of years that it represents

Eon	Era	Period		Epoch	Age (millions of years)		
Phanerozoic	Cenozoic	Quaternary	Neogene	Holocene (Recent)	0.01		
				Pleistocene			
				Pliocene			
		Tertiary		Paleogene	Miocene	5	
					Oligocene	23	
					Eocene	34	
				Mesozoic	Cretaceous	Paleocene	56
						65	
						Jurassic	145
	Triassic	200					
	Paleozoic	Permian	Carboniferous	Epochs are defined for each period although only those of the Cenozoic era are commonly referred to by specific names. Epoch names in other periods are indicated by the adjectives "Early", "Middle", and "Late" with the period name; e.g., Late Devonian Epoch.	251		
					Mississippian	300	
			318				
			359				
			416				
			444				
			488				
			542				
	Precambrian	Proterozoic	Neoproterozoic		542		
Mesoproterozoic			1000				
Paleoproterozoic			1600				
Archean		Neoaerchan		2500			
		Mesoarcean		2800			
		Paleoarcean		3200			
		Eoarcean		3600			
				4500			

Deciphering the relative order of events: application of Steno's Laws

FIGURE Example of sequence of events.

- F. Deposition of units 7 and 8.
- E. Submergence and deposition of unit 6, with the development of an angular unconformity over units 1–4 and a nonconformity over the dike. (In geology, a wavy line, like that between units 4 and 6, is used to signify the presence of an unconformity.)
- D. Episode of erosion.
- C. Regional uplift and folding of preexisting units.
- B. Injection of dike with contact metamorphism of units 1–4.
- A. Deposition of units 1, 2, 3, and 4 and perhaps unit 5.

#4

Deciphering complicated sequences.....

Where to start?????

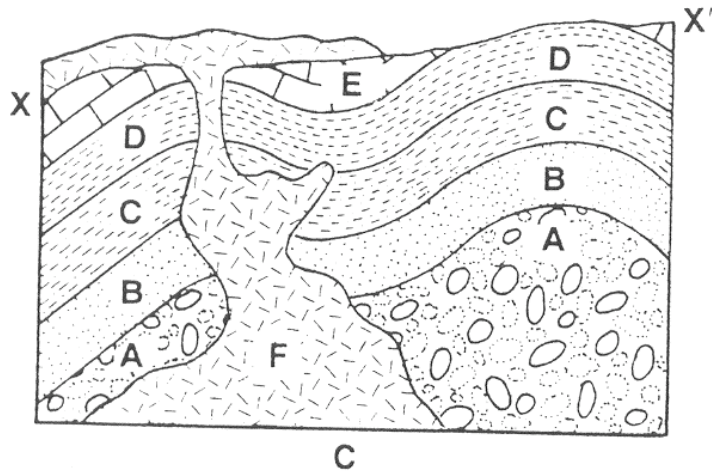

Layers were deposited flat-lying, oldest on bottom

fold

Intrude igneous
rock

Unconformity over igneous
rock and adjacent sedimentary
rock, deposition of more layers

Yes, it's hard to tell if an
igneous rock is folded or not, but the
unconformity associated with it -
the period of time when no sediment
was deposited - is a key

Fault displaces everything

Deposition of last layers which post-date fault, since fault doesn't cut them
