A photograph of a person walking on a steep, grassy hillside during sunset. The sky is filled with soft, golden light and scattered clouds. The person is silhouetted against the bright sky. The hillside is covered in green grass and slopes upwards from the bottom left towards the top right.

Using ^{10}Be to Determine
Sediment Production and
Transport Rates on Steep
Hillslopes in Varied Tectonic and
Climatic Settings

Objectives of this Project

- Establish a new use of cosmogenic nuclides
- Determine nuclide activity in sediment as a function of depth and distance downslope
- Build simple box models of sediment production from rock and subsequent transport downslope
- Determine whether sediment is generated primarily at ridges or whether the rate of sediment production changes downslope
- Determine whether different grain sizes act differently within a hillslope's soil profile

Why?

Hillslopes are often cited as fundamental components of geomorphic systems, but their complexity has discouraged field-based studies.

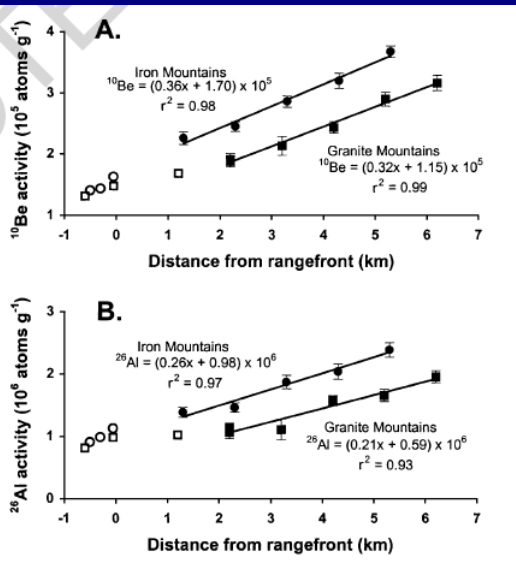

How?

Quantifying Sediment Transport Rates with ^{10}Be

- Previous work done by Nichols et al. (2002) on desert piedmonts

- Common sense tells us that sediment should be generated at range fronts, and subsequently march down piedmont from points of generation

- Concentrations of cosmogenic nuclides in piedmont sediment support this hypothesis showing a direct relationship between distance from range front and and nuclide concentrations

- Will sediment on steep hillslopes show this same relationship? *Stay tuned...*

Sample Collection

Where?

(but those all seem so different...)

Preliminary Results

[Be] x 10⁶ v. Distance Downslope

Preliminary Results

Preliminary Results

[Be] x 10⁶ v. Depth

What's Next?

- sediment production and transport models
- ALSM (LIDAR) and topographic modeling
- comparison of in situ and meteoric Be

Thanks!
